

## SLING HOLDER

### Abstract

A sling holder that when assembled can be secured around a body part to hold an object thereto comprises a strap having first and second ends and a fastener for securing the strap to itself. The strap includes at least one pocket into which the object is placed. The strap is placed around the body part and over the desired portion of the skin. The strap ends are connected to one another, thereby locating and holding the object proximate to the skin in the desired position. The sling holder may be variable in length due to the selective attachment of a plurality of interengageable straps. Fasteners for coupling the straps are interposed between opposing ends of the assembled straps. If multiple straps are employed, any number of pockets may be attached to any number of the straps. An adjustable fastener, an elastic material, and/or a fixedly adjustable extension member may also be employed to adjust the length of the sling holder.
